

Abstract

A system to enable the distribution of interactive content through a computer network. The system includes software to establish a storage and command structure for gathering, storing, and manipulating information associated with an array of subject matters. The information populates a unitary accessible content. The information may, for example, include forum-based communications made available to users through hosts. A transactional server effects the replication of posted information substantially upon posting such that all users accessing the content receive the updated information. Via links may be employed to automatically identify the source of a posting. The system enables filtering, administration, and/or monitoring of the content via the hosts. The system also includes an optional website and mini-page development sub-system that enables application of stored content information directly on a user's or a host's website with minimal indication of origin.
